Abstract: A study of butterfly species diversity was conducted in Chemerong Amenity Forest, Terengganu, Malaysia. A total of 939 individuals from 198 butterfly species were obtained using fruit-baited sweep nets and modified VanSomeren-Rydon cylinder traps. The biodiversity of butterflies in the study area was considered high, with a Shannon index (H') of 4.1, Simpson's index (D_{Simpson}) of 0.042, and Margalef index (I_{Margalef}) of 28.78. Individuals within the community were not evenly distributed among the species ($EShannon = 0.776$). Nymphalidae was found to be the most dominant family (48.5%), and *Lexias dirtea merguia* was the most abundant species recorded with 114 individuals (12%). From the total of eight species protected under Malaysia legislation, one species *Trogonoptera brookiana* was also listed under CITES Appendix II, while only one protected species *Agatasa calydonia calydonia* of the family Nymphalidae (the brush-footed or four-footed) was considered rare. Other rare species found in this study included *Arhopala lucida*, *Caretis saronis sumatrana*, *Miletus nymphis fictus* of the family Lycaenidae (the blues, coppers, & hairstreaks), *Amathusia perakana perakana*, *Bassarona teuta goodrichi*, *Elymnias saueri saueri*, *Elymnias nesaea*, *Mycalesis horsfieldi hermana*, *Mycalesis distanti*, *Ypthima pandocus tahanensis* of the family Nymphalidae (the brush-footed or four-footed), *Celaenorrhinus ladana*, *Erionota sybirta*, *Matapa aria*, *Matapa cresta*, *Matapa druna*, *Pseudokera fulger*, *Taractrocera ardonia*, *Taractrocera luzonensis*, *Telicota linna*, and *Unkana mythea mythea* of the family Hesperidae (the skippers). The dominance of family Nymphalidae may be due to several factors, including high species diversity, widespread distribution and occurrence, as well as the type of bait used in this study. Besides the Genting Highlands and Taman Negara Johor Endau Rompin, butterfly species at Chemerong Amenity Forest are more diverse than other study sites in Malaysia such as Gunung Serambu, Ulu Gombak Forest Reserve, Setiu Wetlands, Kuala Lompat, Bukit Hampuan Forest Reserve, Sungai Imbak Forest Reserve, Tabin Wildlife Reserve, and Ulu Senangang Substation. Further investigation of aspects such as stratification distribution patterns, host plants and forest dwelling species are recommended for better understanding of butterfly communities in the Chemerong Amenity Forest.

Keywords: Biodiversity indices, butterflies, forest reserve, Lepidoptera, primary forest, tropical rainforest.

INTRODUCTION

Studies of butterflies have contributed greatly to the understanding of their ecology, evolution, biogeography, conservation, and usefulness as biodiversity indicators (Sekimura & Nijhout 2019). Knowledge about tropical butterflies is, however, quite limited (Beck 2007; Koh 2007; Bonebrake et al. 2010). In comparison with most temperate ecosystems, tropical forests are characterized by extraordinarily high but poorly-inventoried insect diversity (Bonebrake et al. 2010; Ballesteros-Mejia et al. 2013).

There are 1,182 recorded species of butterfly in Malaysia (Wilson et al. 2015), with 117 being endemic (Tamblyn et al. 2006) and 1,038 species recorded in Peninsular Malaysia (Eliot & Kirton 2000). Continuous monitoring of biodiversity over time is essential to identify changes in species populations. For example, the tradition of recording and monitoring of species occurrences and relative abundance by the Butterfly Monitoring Scheme has provided evidence for declines and losses of some species in the northern temperate zone (Pollard & Yates 1993), while a citizen science project: the 'Peninsular Malaysia Butterfly Count' involved the general public to obtain samples for DNA barcoding of butterflies for monitoring communities in Peninsular Malaysia (Wilson et al. 2015).

Therefore, it is vital to monitor and assess the current status of local biodiversity comprehensively as an action link to the conservation approach and priorities (Green et al. 2003).

Deforestation, together with human population growth increase, have substantial effects on global biodiversity (McKee et al. 2003; Wittmeyer et al. 2008), especially in southeastern Asia. For example, Singapore has recently lost most of its biodiversity due to massive development (Castelletta et al. 2000; Brook et al. 2003; Sodhi et al. 2004; Hau et al. 2005; Sodhi et al. 2010). This concern was also felt in other southeastern Asian countries including Malaysia, which have had high terrestrial degradation in recent years (Sodhi et al. 2010). This is quite worrying as habitat loss is the main cause of butterfly extinction, and diversity is being lost before we can quantify or understand it (Checa et al. 2009).

In the state of Terengganu, butterfly inventory and monitoring were first carried out by Fleming (1975) and also Corbet & Pendlebury (1992). Since then, there have been few studies of butterfly status in the state of Terengganu, and there are deficient sources and publications on this subject (Tamblyn et al. 2006; Yap et al. 2018). Therefore, the diversity and composition

of butterfly at the Chemerong Amenity Forest was investigated. The study site chosen for this study was opportune, as it is proclaimed to be an undisturbed tropical rainforest which houses myriads of flora and fauna species. The results of this study will provide a baseline data on butterflies in the Chemerong Amenity Forest.

MATERIALS AND METHODS

Study Site

The research was conducted at Chemerong Amenity Forest (4.651667, 103.001389) located in the Pasir Raja Forest Reserve, Dungun, Terengganu, Malaysia. It is considered as an undisturbed area with pristine forest. The Chemerong Amenity Forest encompassing of at least 292 ha area and is categorized as a hill dipterocarp forest (Forestry Department of Peninsular Malaysia 2022). This area is blessed with various flora and fauna and is rich with a variety of dicotyledonous plants, namely, Dipterocarpaceae, Rubiaceae, and Euphorbiaceae together with monocotyledonous species such as Zingiberaceae and Palmae (Faridah-Hanum et al. 2006). The amenity forest is well known for the Lata Chemerong waterfall, which is about 305 m in height and the presence of the Malaysia's largest and oldest Cengal tree *Neobalanocarpus heimii* with a height of 65 m, girth of 16.75 m and the estimated age of at least 1,300 years old.

The Chemerong Amenity Forest mainly consists of primary forest. However, due to the status of the area as an amenity forest, the local authority has built several facilities for administration and ecotourism such as an office, cafeteria, toilet, prayer room, camping site, hall, and garden. Various trees and floristic plants were also planted at surrounding areas as decoration. Moreover, a walking trail has also been built in the forest to facilitate tourists to reach the waterfall area.

Data Collection

Sweep sampling method, baits method, and modified VanSomeren-Rydon cylinder trap was utilised to investigate butterfly diversity and composition in Chemerong Amenity Forest from July 2010 to January 2011 (14 days sampling) and August 2011 to January 2012 (10 days sampling). The study was conducted once a month for two days, one-night sampling per effort.

Different collection methods have been used to increase the species diversity of butterflies caught. For instance, some members of subfamily Charaxinae and

Nymphalinae tend to be trapped in the canopy, while Morphinae and Satyrinae in the understory (De Vries 1988). Butterfly collecting was conducted from 0830 h to 1100 h and from 1500 h to 1800 h. Sweep sampling method was conducted by walking in the forest interior, along the trails and garden area at the visitors' complex, and sighted butterflies were captured using sweep net. Baits method on the other hand, was conducted by luring the butterflies using bait that consisted of a mixture of rotten fruits of banana, papaya, apple, orange, and pineapples. The bait was placed on the forest floor at several selected spots such as near the trails, forest fringe and at the forest interior. Lured butterflies were then captured using sweep net.

Butterflies were sampled using modified VanSomeran-Rydon cylinder trap, baited with rotten banana following the method of Rydon (1964). However, the original structure of PVC bait case used by Rydon (1964) was replaced with a plastic plate. To reduce the damage to the trapped samples on a rainy day caused by raindrops, a transparent plastic-sheet was used to cover the top of each trap.

Ten traps were used for each sampling attempts and was positioned about 1 m to 4 m above ground at 10 different selected spots, at the interior of the forest and forest edges. The traps were checked and mixed with fresh baits daily in the morning between 0830 h and 1000 h, and in the evening between 1700 h and 1830 h. The bait was renewed daily by mixing the old bait together with the fresh baits in order to produce the homogenous odour of rotten banana. All butterflies were captured by hand through the zipped part of the trap whilst either resting on the netting or hanging from the cone part of the trap. The butterflies were then killed by using the pinching technique and kept in triangle envelopes. Only butterflies caught using the traps and by sweep net were recorded for this study.

Identification

The samples were identified into species taxon by referring to Otsuka (2001), Corbet & Pendlebury (1992), and Fleming (1975). Revisions were also made by referring to van der Poorten & van der Poorten (2020).

Data Analysis

The diversity, evenness and species richness indices of butterfly communities were assessed and pooled over for two years. Shannon diversity index (H') was applied as a measure of species abundance and richness to quantify diversity of butterfly species. The Shannon diversity index formula is shown below:

$$H' = - \sum_1 \left(\frac{ni}{N} \cdot \ln \left[\frac{ni}{N} \right] \right)$$

where (ni) is the number of individuals of one particular species found in the community, (N) is the total number of individuals for all species found in the community, (\ln) is the natural log and (Σ) is the sum of the calculations.

Next, as a tool to measure species dominance, Simpson's index ($D_{Simpson}$) was used while Margalef index ($I_{Margalef}$) was used to determine species richness, evenness and dominance. The equation for Simpson's index is as follows:

$$D = \frac{\sum_i ni(ni - 1)}{N(N - 1)}$$

Where (ni) is the number of individuals found for particular species in the community, (N) is the total number of individuals for all species found in the community and (Σ) is the sum of the calculations.

For Margalef index ($I_{Margalef}$), the equation is as follows:

$$I = \frac{S - 1}{\ln N}$$

Where (S) is the total number of species and (N) is the total number of individuals found for all species.

To measure equitability or evenness of spread of individuals for each species of butterflies, Shannon evenness index ($E_{Shannon}$) was applied based on the following equation:

$$= \frac{\sum_i \left(\frac{ni}{N} \cdot \ln \left(\frac{ni}{N} \right) \right)}{\ln N}$$

Where (ni) is the number of individuals found for particular species in the community, (N) is the total number of individuals for all species found in the community, (\ln) is the natural log and (Σ) is the sum of the calculations. If the value obtained in $E_{Shannon}$ approaching zero, the distribution of individuals in each species is considered highly similar or even. However, if the value approaches 1, the community did not have evenly distributed number of individuals for each species.

Whittaker plot or a rank abundance curve (RAC) was also generated by using excel to show the relative species abundance, richness and evenness.

RESULTS

Butterfly composition

We recorded a total of six families, 198 species and 939 individuals (Table 1). The most abundant family (Nymphalidae), included 577 (61.4%) individuals, followed by Hesperidae 161 (17.1%) individuals, Pieridae 131 (14%) individuals, Lycaenidae 46 (4.9%) individuals, Papilionidae 15 (1.6%) individuals, and Riodinidae 9 (1%) individuals (Figure 1). The richest genus was *Mycalesis* (9 species), followed by *Arophala*, *Neptis*, and *Eurema* (8 species), *Tanaecia* (7 species), *Amathusia* and *Ypthima*

(6 species), *Graphium* (5 species), and *Euthalia*, *Lexias*, *Charaxes* and *Athyma* (4 species).

Diversity indices analysis

The diversity of butterflies in the Chemerong Amenity Forest recorded a reading of 0.042 for Simpson's index and 4.1 for Shannon-Weiner index with the evenness or equitability of 0.776. These readings indicate that butterfly community in the Chemerong Amenity Forest have very high diversity, yet the equitability of the species can be considered relatively low. However, for the species richness, Margalef index was 28.78 which

Total	Species= 198	939	

indicates high species presence in the study site. Figure 2 summarizes the rank abundance curve for six butterfly families at Chemerong which showed that most of the butterfly species from different families were low ranking species where the number of individuals caught were nearly similar with majority of the butterfly species categorized in low ranking species (106 species or 53.5%) being singletons.

Five species of butterfly were ranked as high-ranking species or dominant species namely *Lexias dirtea merguia* (syn. *maga*), *Lexias pardalis dirteana*, *Ypthima newboldi*, *Cephrenes acalle niasicus*, *Ypthima heubneri*, *Ypthima pandocus corticaria*, *Eurema ada iona*, and *Ragadia makuta siponta*. These dominant species contributed 48% (456 individuals) of the total individuals caught in this study.

DISCUSSION

The dominance by the family Nymphalidae may be due to the generally diverse group of butterfly species in this family. The Nymphalidae contains 7,200 species occurring in all habitats and continents except Antarctica (DeVries 1987; Shields 1989), with 281 species recorded in Malaysia (van der Poorten & van der Poorten 2020). In addition, the use of fruit baits as attractants such as rotting banana, papaya, apple, orange and pineapple were found to successfully attract the *Lexias* butterflies which contributed 22.9% of the total individuals caught in this study. This was supported by Owen (1975), who reported that the baits were effective only for certain genera.

Furthermore, the usage of rotten fruits especially banana as bait have been practiced by many researchers to trap fruit-feeding butterflies (e.g., Hamer et al. 2006;

Barlow et al. 2007; Bonebrake & Sorto 2009; Sáfián et al. 2010). As the strong odour of fermenting fruits can likely be detected at long distances, and in forest environments, it probably forms a reliable cue for locating a fruit fall by these species (Molleman et al. 2005).

In addition, as Nymphalidae is categorized under the fruit-feeding butterflies' guild, the usage of rotten fruits as bait was felicitous which was manifested through the high number of captured individuals and species. However, although fruit-feeding butterflies are defined as those species attracted to fruit bait, this does not mean that fruits are the main food source for all the species in this guild (Molleman et al. 2005). For instance, most tropical Satyrinae are exclusively fruit-feeders, but Charaxinae and Apaturinae are attracted to both fruit and rotting animal matter and excrement (Fermon et al. 2000). Furthermore, fruit-feeding butterflies (including nymphalids) are among the longest-lived Lepidoptera (Molleman et al. 2008). Therefore, longevity and ability to exploit various food resources may be the reasons why family Nymphalidae was the dominant family in this study.

Besides *Lexias* species, a high number of *Cephrènes acalle niasicus* was also caught in this study. One of the reasons which may have contributed to this might be due to the landscape of the study site where ornamental plants such as the Poison bulb *Crinum asiaticum* and White buttercup *Turnera subulata* were planted at the garden area around the visitor complex. These ornamental plants were some of the plants observed to be frequently visited by many butterfly species and eventually contributed to the ease in capturing *C. acelle* and other fast flyer butterfly species.

Other vegetation structures such as meadows, shrubs, grass and lower ground plants were found to be frequently visited by some butterfly genera, namely: *Ypthima*, *Eurema*, *Jamides*, and *Zizeeria*. These butterflies were easily captured at areas close to ground as they obtained protection from winds because of their weaker flight ability. In addition, open areas which offer more light penetration is deemed one of the most visited area by the butterflies to bask under the sun for energy (Van Lien & Yuan 2003). This is proven that, although the developed area and garden area is limited, the occurrence of various surrounding landscape with an array of flora is believed to serve as important habitats for different butterfly species (Asmah et al. 2016; Toivonen 2017).

There were eight species of butterflies categorized as protected under Malaysian legislation, the Wildlife Conservation Act 2010 which were recorded in this

study namely *Agatasa calydonia calydonia* (Glorious Begum), *Charaxes athamas athamas* (Common Nawab), *Charaxes athamas uraeus*, *Charaxes bernadus crepax* (Tawny Rajah), *Charaxes echo echo*, *Idea hypermnestra linteata* (Malayan Tree Nymph), *Prothoe franck uniformis* (Blue Begum), and *Trogonoptera brookiana albescens* (Rajah Brooke).

For *Agatasa calydonia calydonia* (Glorious Begum), it is also considered to be rare in the Malay Peninsula. The two individuals recorded in this study were females and was captured using fruit bait. As for the *Charaxes* recorded, all were singletons except for *C. bernadus crepax* (2 individuals). All individuals were males, and were caught using fruit baits as they are difficult to capture while in flight.

For *Idea hypermnestra linteata* (Malayan Tree Nymph), this species was only seen at some specific trees in the sampling site. Additionally, based on our observation, they are commonly found to be in a group and were caught during mating. Due to their rarity, we speculate that the abundance of this species may depend on its host distribution. Furthermore, the life cycle of this species might also contribute to its rare occurrence as the adults naturally die after laying eggs. Although *I. hypermnestra linteata* has relatively slow flight abilities (Otsuka 2001), it was not an easy task to capture them as they can fly up to very tall trees.

As for *Prothoe franck uniformis* (Blue Begum), 11 individuals of this species were caught during our study with most caught being females (n= 9). Based on our observation, they are strongly attracted to the fruit bait, which is in agreement with Corbet & Pendlebury (1992) whom reported the females to be often seen on fruit bait or on sap from a damaged tree trunk.

The *Trogonoptera brookiana albescens* (Rajah Brooke) population have been reported to be plunging, but the exact status of the population is unknown (Phon & Kirton 2010). The species was rarely observed in this study and only the males were captured. This is since only the males exhibited puddling behaviour by which they tend to aggregate at moist places along forest paths and riverbanks to drink water from which nutrients are obtained (Phon & Kirton 2010). The females by contrast, are forest dwellers and can only be sighted during mating season. This sex disparity is supported by Corbet & Pendlebury (1992). This species is also listed under the Convention on International Trade in Endangered Species of Wild Fauna and Flora (CITES) Appendix II where the trade in this species is closely regulated.

This study also recorded other rare species such as *Arhopala lucida*, *Curetis saronis sumatrana*,

Miletus nymphis fictus of the family Lycaenidae (the blues, coppers, & hairstreaks), *Amathusia perakana perakana*, *Bassarona teuta goodrichi*, *Elymnias saueri saueri*, *Elymnias nesaea*, *Mycalesis horsfieldi hermana*, *Mycalesis distanti*, *Ypthima pandocus tahanensis* of the family Nymphalidae (the brush-footed or four-footed), *Celaenorrhinus ladana*, *Erionota sybiriti*, *Matapa aria*, *Matapa cresta*, *Matapa druna*, *Pseudokerana fulger*, *Taractrocera ardonia*, *Taractrocera luzonensis*, *Telicota linna*, and *Unkana mythea mythea* of the family Hesperidae (the skippers).

Although both *Arhopala lucida* and *Bassarona teuta goodrichi* are common in Langkawi but they are considered to be rare in the Malay Peninsula (van der Poorten & van der Poorten 2020). Similarly, the two *Mycalesis* species are listed as rare, being uncommon to other parts of the Malay Peninsula although *M. horsfieldi hermana* is found in the Tioman group of islands and along the east coast of Johor while *M. distanti* is more common in Kedawi. *Telicota linna* is another species listed as not common to the Malay Peninsula.

For montane species, *Miletus nymphis cresta* is recorded as a rare montane species while *Ypthima pandocus tahanensis* was recorded from Gunung Tahan at elevation of 1650m (van der Poorten & van der Poorten 2020). *Pseudokerana fulgur* restricted to Neomalaya, is another very rare species which is usually observed in the hills.

As for *Amathusia perakana perakana*, it is a rare species that is only found in primary forest while *Erionota sybiriti* and *Unkana mythea mythea* are very rare species that are confined in lowland forest. For both *Elymnias saueri saueri* and *Elymnias nesaea*, these are rare species that are restricted to heavy forest as their habitat (van der Poorten & van der Poorten 2020).

For the *Matapa* species, *M. aria* (Common Redeye) is listed by van der Poorten & van der Poorten (2020) as being not common in the Malay Peninsula, occurring in lowland primary and secondary forests, while *M. cresta* and *M. druna* are rare in the Malay Peninsula lowlands.

As for the other rare species, according to van der Poorten & van der Poorten (2020), *Curetis saronis sumatrana* has only been recorded on the edges of mangrove swamps in Singapore, while *Celaenorrhinus ladana* is very rare with its recorded range being only the Malay Peninsula and Borneo. Both *Taractrocera ardonia* and *T. luzonensis* are also rarely recorded in the Malay Peninsula.

Two major factors are believed to impose great pressure on butterfly populations, namely, habitat loss and an extraordinarily high demand for butterflies by

collectors and commercial dealers (Phon & Kirton 2010), especially for *T. brookiana albescens*. Habitat loss due to timber industries and conversion of extensive area of natural forest for agricultural activities and urbanization, shrink the habitat as well as diminish the host and nectar-plants of this and many other butterfly species.

Comparison of the Shannon-Weiner index results for this study with Kuala Lompat which consists of primary forest located in the Krau Wildlife Reserve, Pahang showed that the diversity of butterfly species in Chemerong Amenity Forest ($H' = 4.1$) was higher than Kuala Lompat ($H' = 3.87$) (Nur Afny Syazwany & Amirrudin, 2014) ($H' = 3.37$) and ($H' = 3.37$) (Zaidi & Abin 1991). Furthermore, the results of butterfly diversity recorded in the Chemerong Amenity Forest (939 individuals from 198 species) were also highest as compared to other study sites in Malaysia namely Gunung Serambu, Sarawak (377 individuals from 97 species) (Pang et al. 2016), Ulu Gombak Forest Reserve, Selangor (194 individuals from 28 species) (Min 2014), Setiu Wetlands, Terengganu (350 individuals from 45 species) (Tamblyn et al. 2006), Kuala Lompat, Pahang (302 individuals from 90 species) (Nur Afny Syazwany & Amirrudin 2014), Bukit Hampuan Forest Reserve, Sabah (42 species) (Chung et al. 2013), Sungai Imbak Forest Reserve, Sabah (174 species) (Jalil et al. 2008), Tabin Wildlife Reserve (136 species) (Akinori et al. 2001) and Ulu Senagang Substation (147 species) (Haruo et al. 2012) yet lower than what was recorded from Genting Highlands, Pahang (2,876 individuals from 214 species) (Min 2014) and Taman Negara Johor Endau Rompin (349 species).

Based on the comparison with other studies, the Chemerong Amenity Forest environment can accommodate more diverse species of butterflies. This can be proven if the sampling period was extended and the study site not only focuses on the lowlands (not more than 200 m above sea level) but includes different elevations (more than 200m above sea level). Nevertheless, Chemerong can be considered as pristine forest and the introduction of certain ornamental plants in the garden area plays an important role as attractant for the various species of butterflies such as *Papilio memnon agenor*, *Catopsilia pomona pomona*, and many Hesperidae butterflies.

Conclusion and Recommendations

In general, short-term sampling with limited manpower and equipment was considered satisfactory, although it only provides a snapshot of the butterfly community present in the Chemerong Amenity Forest. The presence of endangered butterfly species which are

protected under the Malaysian Wildlife Conservation Act 2010 increases the conservation value of the Chemerong Amenity Forest as a forest reserve in Malaysia. A much longer term sampling is strongly recommended to further observe and examine butterfly species at different elevations, across different seasonality and years, as well as further exploration of forest canopy to reveal more species in that stratum. The rapid loss of primary forest habitats and the growth of oil palm plantations in many areas of Malaysia as well as in the state of Terengganu underline the urgency with which this work needs to be undertaken.

Author details: MUHAMMAD

HAFIZ SULAIMAN is a PhD student at the Faculty of Science and Environment, Universiti Malaysia Terengganu (UMT). He obtained his MSc in ecology and is currently pursuing his PhD in Wildlife Management, particularly on the conservation and management of the Sunda Pangolin in Peninsular Malaysia. ABDUL MUNIR MOHD ZAKI obtained his MSc from Universiti Kebangsaan Malaysia (UKM) on fruit fly behaviour for his MSc project and is currently pursuing his PhD on Thysanoptera diversity associated with starfruit (*Averrhoa carambola*) across Peninsular Malaysia at the Institute of Science Biology, Faculty of Science, University of Malaya (UM). YAP GEOK CHIN and NUR ATIQA ANIRUDDIN were former undergraduate students at the Faculty of Science and Marine Environment, Universiti Malaysia Terengganu (UMT). Both studied butterfly diversity for their undergraduate project respectively. JU LIAN CHONG is currently based at the Faculty of Science and Marine Environment, Universiti Malaysia Terengganu (UMT) as an Associate Professor. She studies various species of fauna including pangolins, lepidoptera and other mammals, on aspects of their ecology, biology and populations to better understand the intricate interactions between organisms and their ecosystem.

Author contributions: All

authors discussed the results and contributed to the final manuscript. Muhammad Hafiz Sulaiman, Abdul Munir Mohd Zaki and Chong Ju Lian wrote the manuscript with support from the rest of the authors. Muhammad Hafiz Sulaiman and Chong Ju Lian conceived the original idea for this paper and revised the main conceptual ideas, while Abdul Munir Mohd Zaki, Yap Geok Chin and Nur Atiqah Aniruddin gave feedback to improve the paper.

Article

Distribution, diet, and trophic level of *Arvicanthus abyssinicus* and *Tachyoryctes splendens* around the area of recently extinct Ethiopian Wolf *Canis simiensis* on Mount Guna, northwestern Ethiopia

– Hirpasa Teressa, Wondimu Ersino & Tadele Alemayo, Pp. 20539–20549

Communications

Seasonal composition of avian communities in different habitats of Harike Wetland, a Ramsar site in Punjab, India

– Jagdeep Singh & Onkar Singh Brraich, Pp. 20550–20565

Temporal changes in species richness of waterfowl (Anseriformes) community in D’Ering Memorial Wildlife Sanctuary, Arunachal Pradesh, India

– Tapak Tamir & Daniel Mize, Pp. 20566–20575

Reptilian assemblages in the wetlands of Amboli hill complex, northern Western Ghats, Maharashtra, India during the monsoon season

– Sachinkumar R. Patil & Kiran Choudaj, Pp. 20576–20583

Butterfly diversity and composition at Chemerong Amenity Forest, Terengganu, Malaysia

– Muhammad Hafiz Sulaiman, Abdul Munir Mohd Zaki, Geok Chin Yap, Nur Atiqah Aniruddin & Ju Lian Chong, Pp. 20584–20596

Ecological niche modeling for reintroduction and conservation of *Aristolochia cathcartii* Hook.f. & Thomson (Aristolochiaceae), a threatened endemic plant in Assam, India

– Bhaskar Sarma & Bhaben Tanti, Pp. 20597–20605

New host plant records of Fig Wax Scale *Ceroplastes rusci* (Linnaeus, 1758) (Hemiptera: Coccomorpha: Coccidae) from India

– Arvind Kumar & Renu Pandey, Pp. 20606–20614

Seasonal variations influencing the abundance and diversity of plankton in the Swarnamukhi River Estuary, Nellore, India

– Krupa Ratnam, V.P. Limna Mol, S. Venkatnarayanan, Dilip Kumar Jha, G. Dharani & M. Prashanthi Devi, Pp. 20615–20624

Short Communications

First record of *Prosopeonoides* Millidge & Russell-Smith, 1992 (Araneae: Linyphiidae) from India, with the description of a new species

– Anusmitha Domichan & K. Sunil Jose, Pp. 20625–20630

Rediscovery of *Platerus pilcheri* Distant (Hemiptera: Reduviidae), a forgotten assassin bug from India, with comments on its range extension

– H. Sankararaman, Anubhav Agarwal, Valérie A. Lemaître & Hemant V. Ghatge, Pp. 20631–20636

First Indian DNA barcode record for the moth species *Pygospila tyres* (Cramer, 1780) (Lepidoptera: Crambidae: Spilomelinae) distributed in Asia and Australia

– Aparna S. Kalawate, A. Shabnam & K.P. Dinesh, Pp. 20637–20642

First record and description of female *Onomarchus leuconotus* (Serville, 1838) (Insect: Orthoptera: Tettigoniidae) from peninsular India

– Sunil M. Gaikwad, Yogesh J. Koli & Gopal A. Raut, Pp. 20643–20647

New records of odonates (Insecta: Odonata), *Archibasis oscillans* Selys, 1877 and *Merogomphus tamaracherriensis* Fraser, 1931 from Maharashtra, India

– Akshay Dalvi & Yogesh Koli, Pp. 20648–20653

A checklist of dragonflies & damselflies (Insecta: Odonata) of Kerala, India

– Sujith V. Gopalan, Muhamed Sherif & A. Vivek Chandran, Pp. 20654–20665

***Aldama macbridei* (Heliantheae: Compositae): notes on its distribution and vulnerable habitats in central Peru**

– Daniel B. Montesinos-Tubée & Federico García-Yanes, Pp. 20666–20671

Lichens and animal camouflage: some observations from central Asian ecoregions

– Mahmood Soofi, Sandeep Sharma, Barbod Safaei-Mahroo, Mohammad Sohrabi, Moosa Ghorbani Organli & Matthias Waltert, Pp. 20672–20676

Notes

First photographic evidence of Asiatic Black Bear *Ursus thibetanus* in Kaziranga Tiger Reserve, India

– Priyanka Borah, Jyotish Ranjan Deka, Mujahid Ahamad, Rabindra Sharma, Ruchi Badola & Syed Ainul Hussain, Pp. 20677–20679

First record of Small Minivet *Pericrocotus cinnamomeus* (Aves: Passeriformes: Campephagidae) from Kashmir, India

– Zakir Hussain Najar, Bilal A. Bhat & Riyaz Ahmad, Pp. 20680–20682
